# Commodity Market Outlook 

Jim Hilker<br>Professor and MSU Extension Economist<br>Department of Agricultural, Food, and Resource Economics<br>Michigan State University

# Market Outlook Reports <br> For December 4, 2017 

(Written December 4, 2017 for release in Michigan Farm News Dec. 15)

Relative too much of the past ten years corn, wheat, and soybean prices have shown little volatility over the past few months, especially since harvest began. This relative price stability would be expected when you enter the marketing year with large beginning stocks and expect to end the marketing year with large ending stocks in all three of these major commodities. And this is even more likely when the rest of world is in the same situation, as it pretty much is.

The next question is this likely to last? One way of looking at that question, especially with storable commodities, is to look at the next marketing year out, which would be 20182019. And this is what I do in this issue. The USDA just released their preliminary 10 year price forecast for a number of major commodities, and while I am only forecasting a likely 2018-19, versus 10 years, the USDA 2018-19 forecasts for corn, wheat, and soybeans, while somewhat different than mine, tells the same story. Basically, without a significant production shortfall, or an unlikely new demand surge, such as the new ethanol demand ten years ago, stability to gradually getting back up to the costs of the most efficient producers is the most likely scenario.

As I look at relative returns per acres in 2018-19 for the country as a whole, soybeans appear to have a slight advantage, second would be corn, and third would be wheat. I am basing this on today prices, for both now and for new crop, and costs remaining fairly steady. This is not to say other crops do not play a role, they do, and will affect planted acreage of the big three. But I don't see the total acreage planted of the big three changing much, given returns to other crops.

## CORN

Given the above statement on relative prices I expect planted corn acres to remaining about the same to fractionally down. I you can see in Table 1, I lower 2018 planted corn acres a smidgen. We have already made a substantial move to soybeans and away from wheat.

I have used a trend corn yield using 1989-2017, long enough to take out odd years, and short enough to account for the new technology. While the $171.3 \mathrm{bu} / \mathrm{ac}$ I use is lower than the last two record years it would be the third highest on record. This would give us the fourth highest production on record. But even with bigger beginning stocks total supply would be down 1\%, but still massive, and the third highest on record.

And then we come to demand, how much of the massive supply do we expect to use at the expected price as shown in Table 1. I expect livestock numbers to increase marginally, and have increased projected corn for feed use a bit less marginally as $I$ expect a slight increase in prices. Ethanol continues to be profitable on the margin, so I expect corn for ethanol use will grow in 2018-19 about what it grew in 2017-18. Other industrial uses are expected to grow at their recent rate. The projected 12,590 million bushels would be record domestic use.

Given trend yields and expected economic growth in the rest of the world, I expect exports to be about the same as last year. With a slight upwards bias. This would make total use 14,525, just under the record use in 2016-17, which was due to higher exports with the short Brazilian corn crop in that period.

This would put expected ending stocks at 2187, down a bit from the last two years, but still a relatively large 15\%. This would put my 2018-2019 annual average weighted price at \$2.45.

## WHEAT

While returns to wheat generally lag behind corn and soybeans, due to rotations, spreading of workloads, and some areas, such as low moisture regions, are much more conducive to wheat then corn and soybeans. So I think the cuts in wheat acres will slow and then stop over the next few years. I am suggesting the planted wheat acreage for 2018 harvest will be 45.5 million acres, down a half million from 2017. And using a trend yield of 46.9 bu/ac, production would be 1,819 million bushels, up 78 million bushels from 2017 with a half bushel better expected yield. But when you add on the smaller beginning stocks, total supply would be down 4\%. See Table 2.

I project total use to be down $2 \%$ with exports struggling to get to the projected 2017-18 levels which are expected to be down a little from the 2016-17 levels. Food use has been stagnant and is expected to stay that way. With feed use projected to be about the same to being up a little as shown in Table 2.

This would leave ending stocks at 810 million bushels, with stocks to use being $38.7 \%$, the lowest since 2014-15. This compares with $43.8 \%$ in 2017-18. The expected annual average weighted price with this scenario would be $\$ 4.75$, up 15 cents per bushels.

## SOYBEANS

While I expect producers will plant soybeans with the expectation they will have the highest relative returns, is not to say returns to soybeans are expected to be good. I project planted soybean acres for 2018-2019 will be 91 million acres, up 800,000 acres from what was planted for the 2017 crop. I use a trend yield of 48.4 for soybeans planted for the 2018 crop. This would give us the second largest crop on record, just below the record 2017 crop. Almost as big a crop, and much larger beginning stocks, would make total supply for 2018-19 a new record, up a little over 1\%.

Soybean use is expected to be up close to $2 \%$. Crushings are expected to be up 15 million bushels as livestock protein needs are expected to grow with more livestock and dairy on feed. And oil demand will hang in there with income grow, population growth, and biodiesel returns.

Exports are expected to grow $3 \%$ as China expects their soybean imports to grow close to $4 \%$ a year. And China takes about 63\% of the U.S soybean exports, as they do they rest of the worlds. The total would but total use at a record 4,401 million bushels. The greater increase in use than total supply means ending stocks would drop.

Ending stocks to use are expected to be 9.2\%, down from the projected 2017-18 level of 9.8\%, but up from the 2016-17 7.1\% of use. This would put the expected annual average weighted price at $\$ 9.35$, up 5 cents per bushel relative to the projected 201718 price. This would indicate fairly stable prices and relative low returns is the likely scenario.
