## MISSION STATEMENT

The mission of *Sugarbeet Advancement* is to generate research and utilize education to enhance productivity and profitability of the Great Lakes sugar beet industry. This will be accomplished through a cooperative effort involving Michigan State University, Michigan Sugar Company, Producers and Agribusiness. The *Sugarbeet Advancement* Committee will be active in identifying research needs, conducting educational programming, and identifying promotional and financial support to accomplish established goals.

*Partnership

## ACKNOWLEDGEMENTS

### ON-FARM RESEARCH AND DEMONSTRATION

The Sugarbeet Advancement Committee is pleased to provide you with the Tenth Edition of the "Sugar Beet Research and Demonstration Report." The Sugarbeet Advancement efforts and priorities are directed by a 24 member committee. These members identify researchable issues that limit yield and profitability to Michigan Sugar Company members. The majority of research is uniquely conducted on farm in larger strip trials. This research has earned the confidence of growers and has served as a conduit to improve the speed of acceptance of new production practices.

In 2006, Michigan Sugar Company produced 3.8 million tons of beets. A record yield of 23.5 tons per acre and 18% sugar was achieved even though a September 15<sup>th</sup> early harvest was initiated and crop loss occurred due to excessive rainfall in some areas. Many fields in ideal growing areas produced 30 plus ton yields. Certainly ideal weather in many areas allowed us to achieve high yields. However, these yields would not have been as high if growers had not adopted better management practices from research conducted by Sugarbeet Advancement, Michigan Sugar Company and Michigan State University researchers. The 2006 experience certainly gives notice that a higher yield bar of 30 tons and high quality is achievable.

Research conducted this year by Sugarbeet Advancement included many high yielding fields but also involved several trials that were abandoned due to water damage. For this reason, it is imperative that the growers read the comments on each trial, know the trial reliability and utilize the statistical analysis. Statistical analysis is extremely important to understand if the differences that are seen are real or just trial variability. Every attempt is made to locate high quality sites and produce high quality data. If you have specific questions on trials, feel free to give us a call.

It seems impossible that Sugarbeet Advancement has been functioning for ten years. Yields in 1995-1996 were at 15 tons for two years running. Our goal was to improve yields to 20 tons. Yield increases have averaged about 8/10<sup>th</sup> of a ton per year. Michigan has led the nation in improvement of gross sugar per acre. In the future, we do expect tonnage to continue to improve with increased emphasis on high quality. The industry has a special appreciation for the cooperators that allow the field research conducted by Sugarbeet Advancement. From these sacrifices, large gains have occurred for the betterment of the industry.

Sugarbeet Advancement is always looking for grower input. We encourage you to contact any committee member with production concerns of the industry.

Sincerely,

Alan Sherwood  
Sugarbeet Advancement Chair

## PREFACE

The Data in the 2006 *Sugarbeet Advancement* Research and Demonstration Book can be a valuable tool for making production decisions on your farm. Producers must understand the terminology to draw correct conclusions. Most of the research demonstration trials are replicated three or four times, either in a randomized format or complete randomized block. These trials have a statistical analysis run on them. Trials, which were not randomized and/or replicated, are considered as demonstrations with no statistical analysis run. The following comments should be helpful in your understanding of the results.

**TREATMENT NAME** -- Identify different named treatments in the trial.

**RWSA** -- Recoverable White Sugar Per Acre. This number is calculated by multiplying recoverable white sugar per ton by actual yield per acre. All reported numbers are rounded to the nearest pound.

**ACTUAL YIELD T/A** -- Tonnage calculated on per acre basis. Reported number is rounded to one-hundredth decimal point. Gross tons (no tare off).

**RWST** -- Recoverable White Sugar Per Ton incorporating sugar and clear juice purity. Reported number is rounded to the nearest pound. This is based on a 120-day slice (not fresh basis).

**% SUGAR** -- Percentage Sugar Content of Beet; rounded to the one-tenth decimal point.

**% CJP** -- Percentage Clear Juice Purity; rounded to the one-tenth decimal point.

**RHIZOCTONIA BEETS** -- Average number of dead or dying beets from Rhizoctonia Crown Rot per indicated length of row.

**POPULATION** -- In monitoring trials, approximately 10- 20- and 30-day plant counts were taken to monitor emergence of each treatment. Results are reported on beets per 100 foot of row.

**HARVEST POPULATION** -- Beet population was taken after beet defoliation. All crowns were counted, including small beets, which may not be picked up by harvesters.

**AVERAGES** -- Use averages to compare treatments which are better or worse than average of trial.

**LSD 5%** -- Least Significant Difference at the 95% confidence level in which one treatment compared to another is actually different. This calculation is used to take into account soil variation and other factors. NS indicates differences between treatments are *Not Significant*.

**C.V. %** -- Coefficient of variation is an indicator of how much variation is in the trial. If C.V.'s are 5% or less, it is considered an excellent trial; 10% or less is a good trial; 15% is fair, and etc. The less variation the more reliable the results are.

\* **1X - 2X - 3X** -- Indicates how many times a practice was done.

**Comments: High yield environment.** Trial planted under good soil conditions. Stand establishment was rapid and timely rainfall occurred all season. This was an exceptional looking field with minimal yield constraints. Excellent leafspot control and low levels of Rhizoctonia. Populations were very high with some varieties above optimum levels. Average harvest population was 57,000 plants per acre. VARIETY 73 RZ had a planter plate seed size mismatch that cause a lower population.

**Comments:** Trial planted in high residue corn stalks. Field was planted under good soil conditions with excellent emergence. Heavy rainfall occurred after emergence which slowed the growth of beets. Very low amount of Rhizoctonia found in field. Leafspot control was good. Trial looked good all year. There was minimal seedling disease. Harvest population was 35,000 plants per acre.

**Trial Reliability:** EXCELLENT

**Comments: High Yield Environment.** Emergence was rapid under warm soil conditions. Leaf spot control was good. Some Rhizoctonia Crown Rot was present; however, one replication did have a significant level in some varieties. There was some seedling loss from the 21 to 30 day stand count and further significant stand loss up to harvest for some varieties. Trial was harvested under wet conditions. Average harvest stand was 29,000 plants per acre.

**Trial Reliability: VERY GOOD**

**Comments:** Trial was slow to emerge. Field was planted under good soil conditions. Dairy manure was applied in the fall before beet planting. Rhizoctonia and seedling diseases were minimal. Leafspot control was fair to good. Weed control was a problem especially with small canopy beet varieties. Average harvest populations was 39,000 plants per acre.

**Comments:** Trial had crusting problems which caused the slow/weak emerging varieties to not establish good stands. Beet seedlings stressed, along with some seedling disease observed. Trial planted under good soil conditions but crusted after heavy rainfall. Rhizoctonia pressure was variable from light to moderate. A low to moderate amount of Aphanomyces scarring was seen on the roots. Cercospora leafspot control was fair to good. Harvest population was approximately 18,700 plants per acre. VARIETY 73 RZ had a planter plate seed size mismatch which caused lower population.

**Trial Reliability: FAIR**

**Comments:** Trial was conducted to look at a nematode resistant variety compared to a susceptible variety. Nematodes were present, but low levels were found on beets and in soil samples. This was a very high yield environment. Leafspot control was fair/good for B-5534 N. A small but significant tonnage improvement occurred utilizing the nematode resistant variety under low level populations.

**Trial Reliability: Excellent**

**Comments:** Nematodes were present at moderate to high levels. Variety B-5534 N had severe leafspot that caused burn down and high levels of Rhizoctonia Crown Rot. Variety B-5534 N is a high management variety that needs Quadris for Rhizoctonia Crown Rot control and additional leafspot sprays over standard varieties.

**Trial Reliability:** EXCELLENT

C.V. (%)	2	1.75	1	1.4	.1					

**Comments:** This is a high yielding trial. Trial was conducted to compare B-5534 N, a nematode tolerant variety to B-5833 R, a susceptible variety. **No nematodes were found in the field.** Four spray program gave excellent leafspot control in both varieties. Tonnage yields of both varieties were identical in the absence of nematodes. In the absence of cyst nematodes there is no advantage of planting B-5534 N. Four leafspot sprays were needed to control leafspot; it is susceptible to Rhizoctonia and is a lower quality beet.

**Comments:** Trial/demonstration was conducted to look at the effect of Oil Seed Radish and clover in a field that was highly infested with sugar beet cyst nematode. Clover was established in wheat two years ago. Summer radish was established in wheat stubble and spring radish was established in the wheat as a frost seeding in 2004. In the early spring of 2005, the whole field was seeded to oilseed radish and killed prior to dry bean planting. Each strip was 60 feet wide the entire length of the field. Field was split with a nematode resistant variety (B-5534 N) and a susceptible variety (B-5833 R). Variety B-5534 N highly susceptible to leafspot. Increased yield improvement also occurred when oil seed radish was used and also when clover was used. The largest response occurred in the susceptible variety and a smaller response was seen in the resistant variety. This trial demonstrates that up to 13 ton yield increase can occur in nematode infested fields by combining resistant varieties, oil seed radish and clover in rotation.

**Comments:** Trial was conducted to compare and evaluate traditional priming (PAT) to a new priming method called X-BEET from GTG. All seed treated was from the same seed lot. Prior to emergence, a heavy rainfall occurred that formed a significant crust. Trial was crust busted with a quad-runner. X-BEET was significantly faster in emerging than traditional PAT and non primed CHECK seed. Faster emerging seed was better able to emerge through the crust before it hardened which produced a significantly higher yield. Low population beets have reduced quality and tonnage.

**Comments:** Trial was conducted to evaluate traditional priming (PAT) to a new priming technique called X-Beet. All seed treated from the same seed lot. Some rainfall occurred after planting causing a tight soil condition that then dried to become very hard. Faster emerging X-Beet was better able to emerge and establish a stand than PAT or standard Check treatments. X-Beet produced a significantly higher tonnage and improved quality. See picture centerfold and graph for complete emergence data.

**Comments:** Trial was originally conducted to evaluate a new proprietary priming process developed by GTG called X-Beet compared to traditional PAT and non-primed treatment. After planting, heavy rainfall occurred causing a crusting situation on all treatments. Because of faster speed of emergence than other treatments, only the strips of X-Beet established a marginally acceptable stand of 105 beets per 100 foot of row. Cooperator was able to direct replanted beets in only the Check and PAT beets that did not establish (30 days later). Seed used for replants was the same seed (X-Beet, C-963) that was used in the original planting. Replanted beets emerged and established a final stand of 200 beets per 100 foot of row. This population was double the non replanted X-Beet. Data indicated no significant difference of replanting a marginally thin stand of beets (105 beets/100ft) 30 days after planting if weed control can be maintained.

**Comments:** Trial was conducted to compare the control of Rhizoctonia when using full and half rates of Quadris in furrow at planting. Rates were approximately 10.5 and 5.25 oz/acre. Rhizoctonia levels were low to moderate. Trial results and yield was greatly affected by high levels of sugar beet cyst nematode. No significant differences were measured at the 95% confidence level. Some trends did emerge such as: Full rate of Quadris may slow down emergence but did not affect final stand. As Quadris rate increased, Rhizoctonia levels trended down. This data should be used with caution!

**Comments:** Trial was conducted to look at the effect of In Furrow, 2x2 and combinations of In Furrow and 2x2 fertilizer applications. Soil test indicated Phosphorous levels at 66 ppm/high levels. Fertilizer application rates for In Furrow was 4.6 gallons per acre and any 2x2 applications were 15 gallons per acre. Ag Spectrum was applied in combination with Grozyme and Kick Off. Definite visual response (larger leaf) area was seen with either 28% or 10-34-0 applied 2x2. With In Furrow applications alone, visual response was not seen. In Furrow applications did generally slow emergence and in some cases reduced stand when applied at the 4.6 gallon rate. (See photo in center of book)

**Comments:** This trial was conducted to evaluate a one and two fungicide spray program on a new highly tolerant leafspot variety (C-355). Twelve replications were combined including corn/soybean previous crop and conventional/zone till tillage systems. Leafspot control was considered good with either the one or two spray interval. Observation strips left on the outside of the trial with no fungicides applied had significant leafspot. No significant differences were measured in quality or tonnage. It appears that growers may be able to reduce and/or possibly delay fungicide applications when utilizing this variety. There are large differences in leafspot inoculums in the Great Lakes growing region. Other areas may require more or less sprays than indicated in this trial. Utilize Michigan Sugar Company data to further evaluate this variety.

**Comments:** Trial was conducted to evaluate and compare producing sugar beets utilizing conventional fall moldboard plow with one time spring tillage, to a conservation system of fall zone building with direct planting in the spring. Corn and soybeans were previous crops to beets. Ideal stands were established with both tillage systems. No significant differences were measured in RWSA or Tons. This trial was incorporated the latest in technology utilizing GDD's and DSV from BEETCAST to time herbicide and fungicide sprays. Weed control was excellent and leafspot control was also good with either one or two sprays when using a highly resistant variety (C-355). Pre side dress nitrate testing was followed. A total of 41 pounds of actual Nitrogen was applied when the previous crop was soybeans and 100 lbs. with corn.

**Trial Reliability: GOOD**
